

5G_Conspiracy_Graphs

1- Number of nodes and edges

Nodes → 58

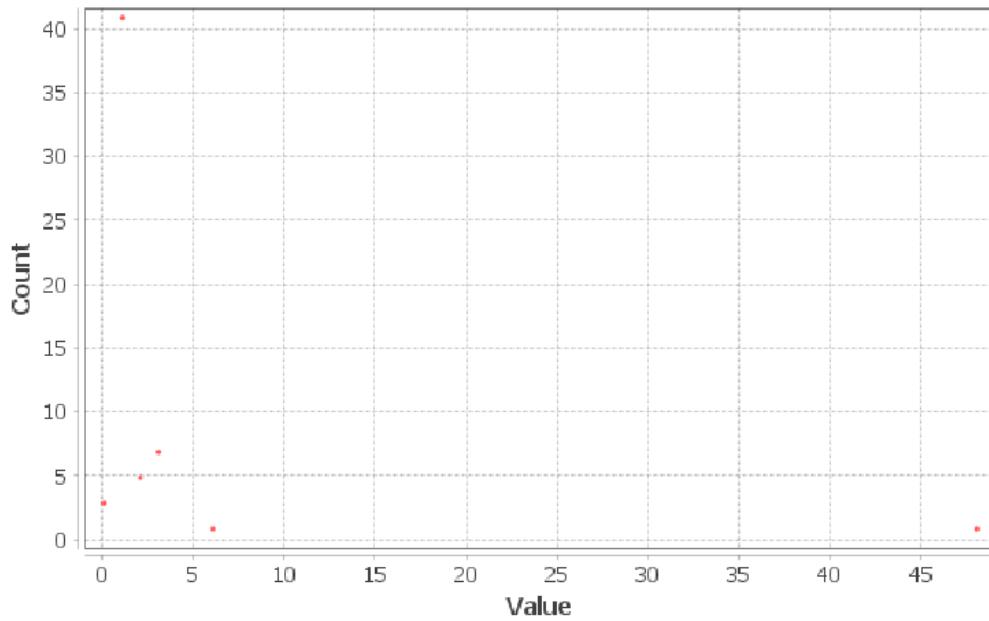

Edges → 63

2- Average Degree → 1.086

Results:

Average Degree: 1.086

Degree Distribution

3- Graph Density → 0.019

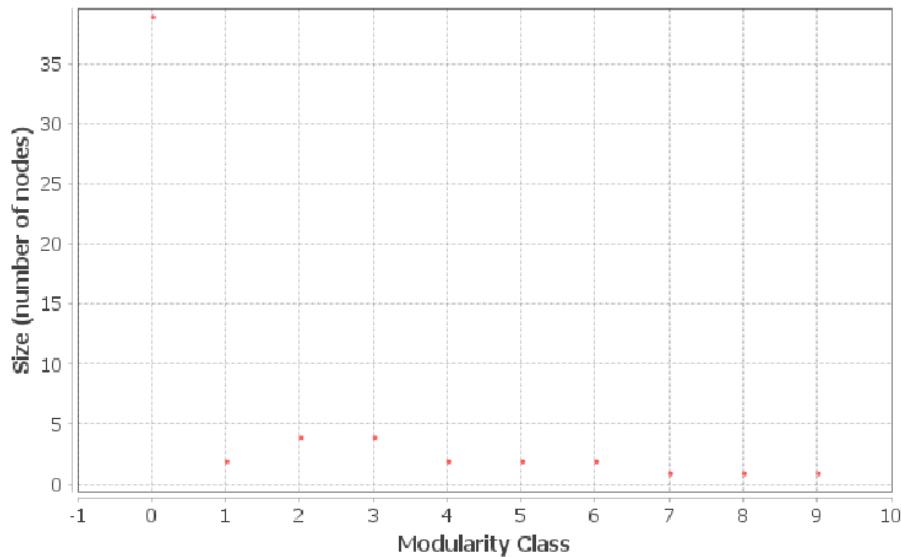

4- Average clustering coefficient → 0.037

5- Modularity → 0.264

Results:

Modularity: 0.264
Modularity with resolution: 0.264
Number of Communities: 10

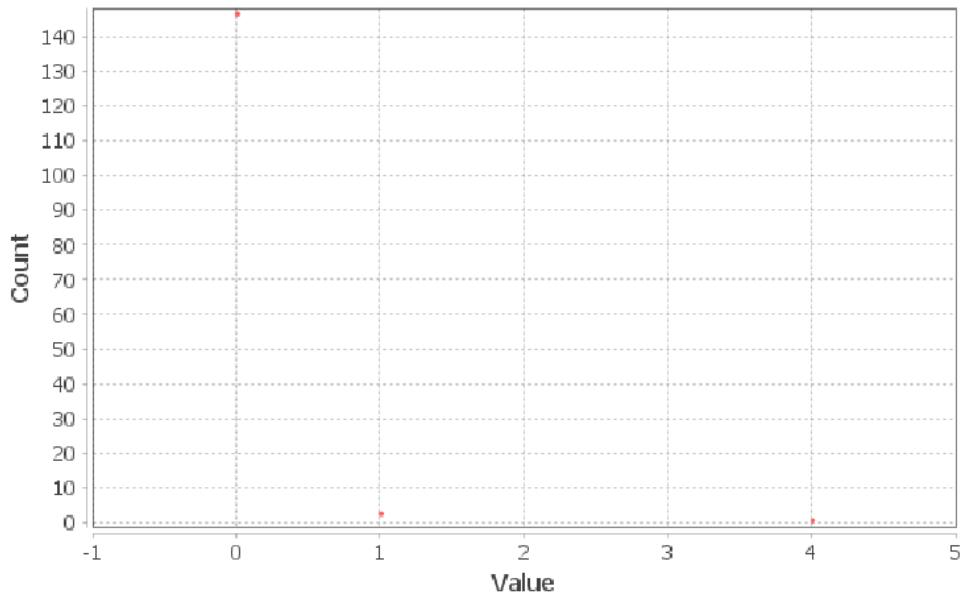

Size Distribution

6- Betweenness and closeness centrality →

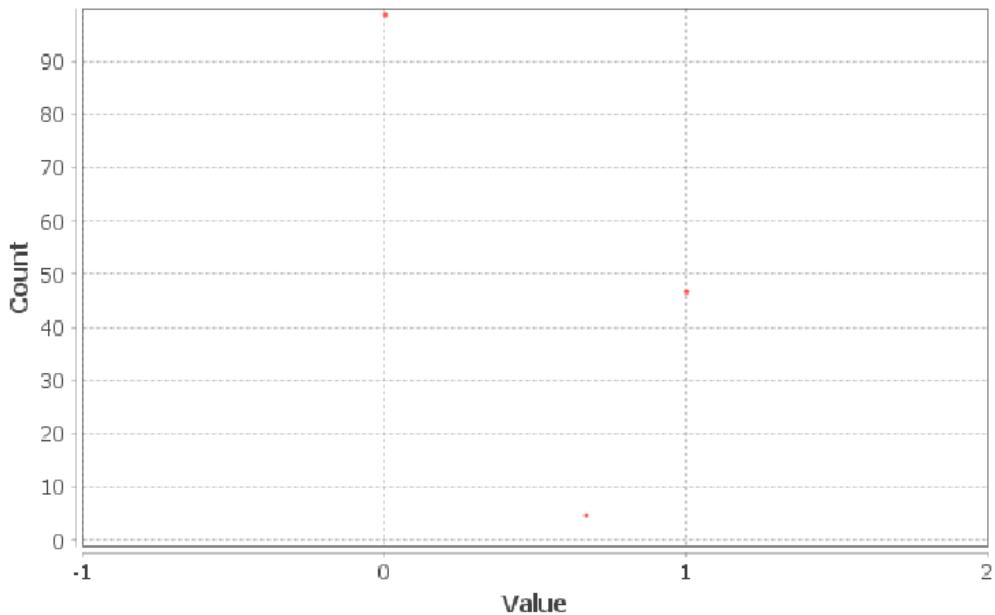

Betweenness → 0.0874

Betweenness Centrality Distribution

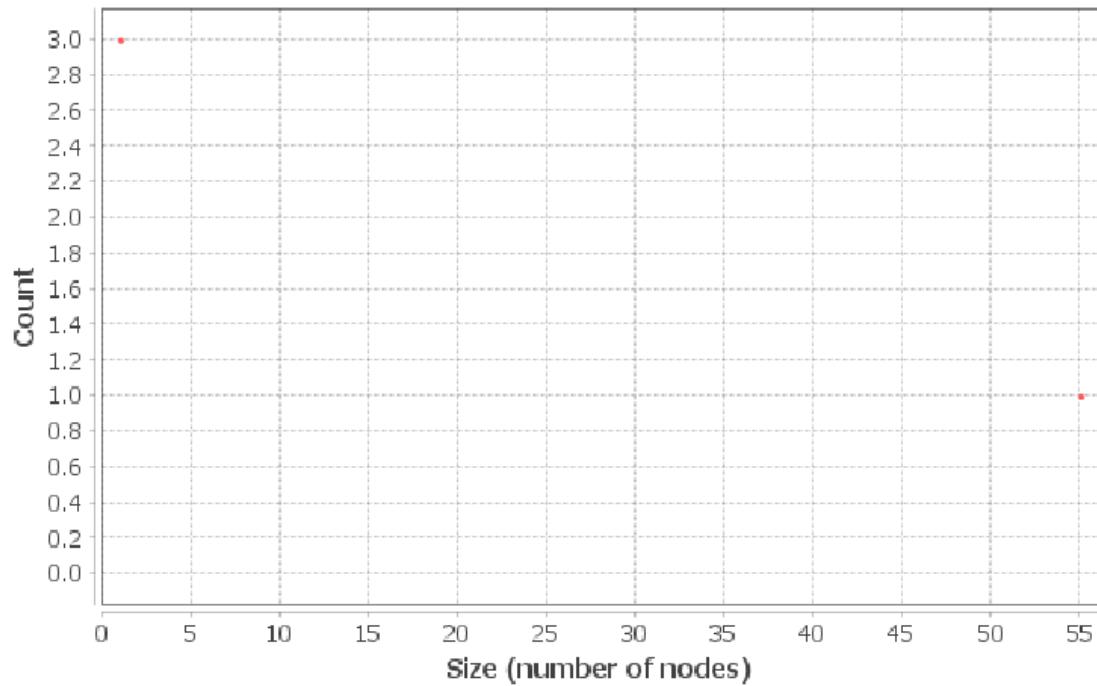

Closeness → 0.312

Closeness Centrality Distribution

7- Connected Components → 4

Size Distribution

Non_Conspiracy_Graphs

1- Number of nodes and edges

Nodes → 93

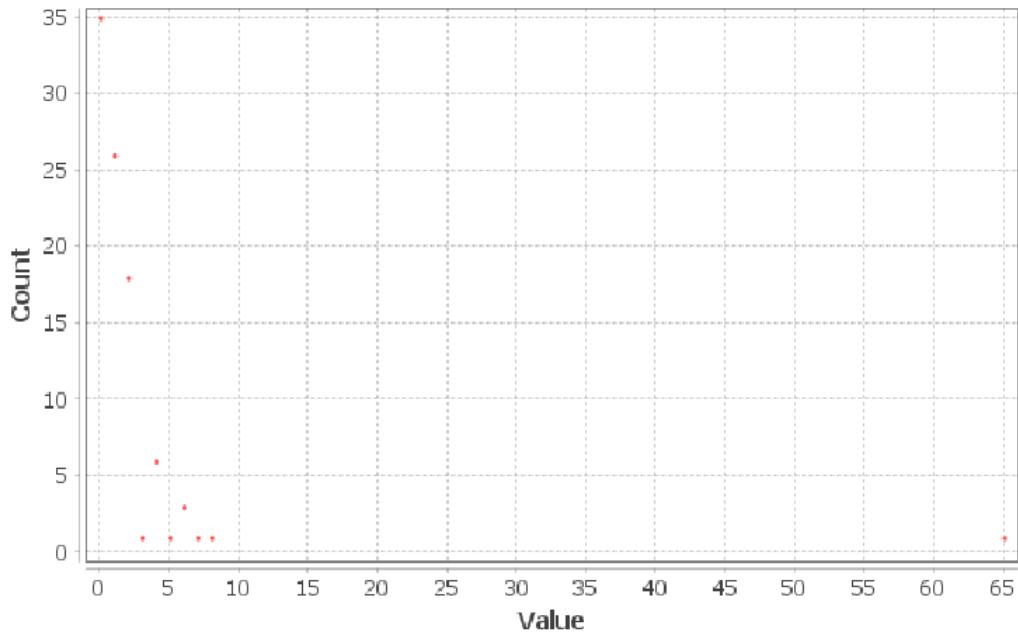

Edges → 96

2- Average Degree → 1.032

Results:

Average Degree: 1.032

Degree Distribution

3- Graph Density → 0.011

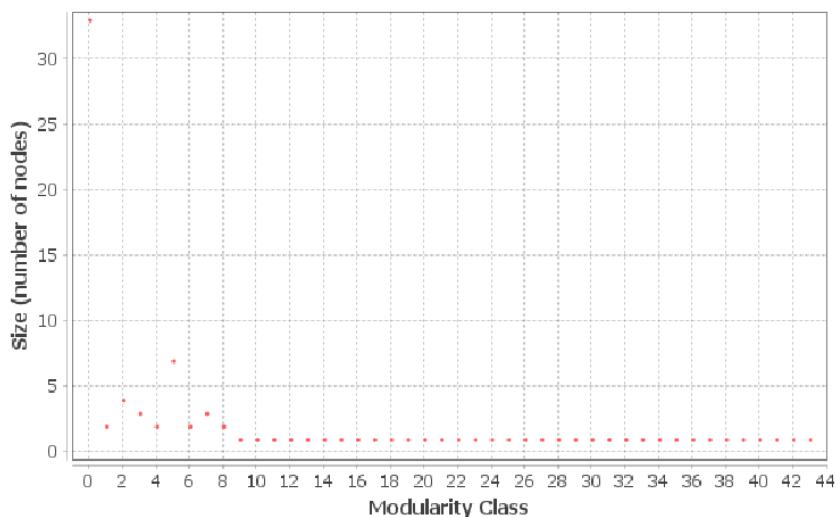

4- Average clustering coefficient → 0.065

5- Modularity → 0.264

Results:

Modularity: 0.375
Modularity with resolution: 0.375
Number of Communities: 44

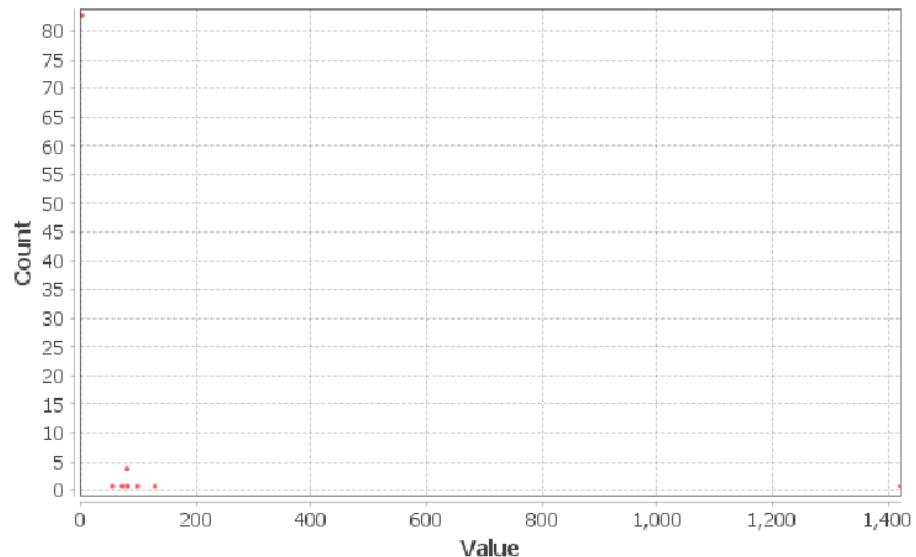

Size Distribution

6- Betweenness and closeness centrality

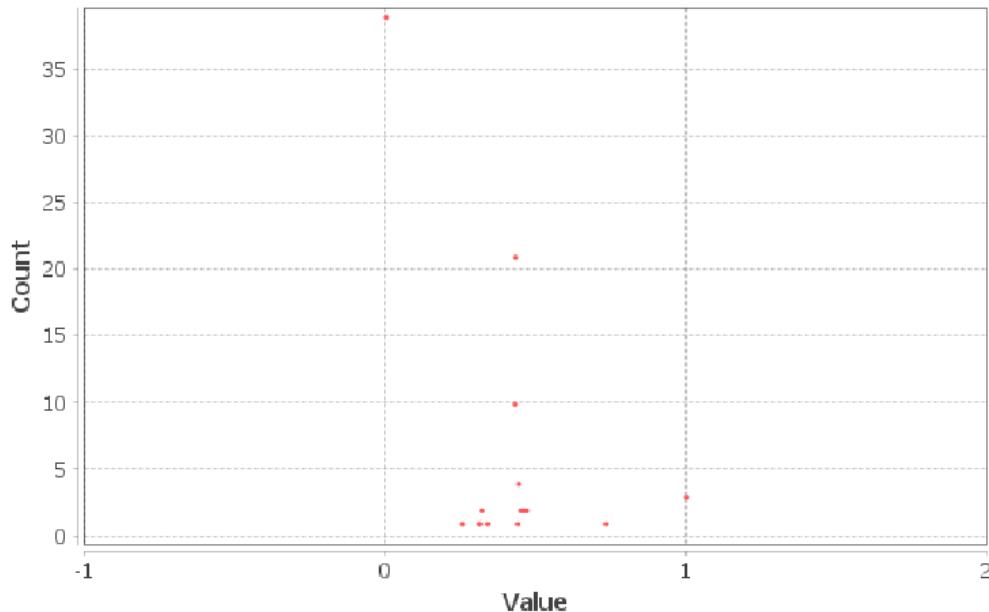

Betweenness → 0.0412

Betweenness Centrality Distribution

Closeness → 0.378

Closeness Centrality Distribution

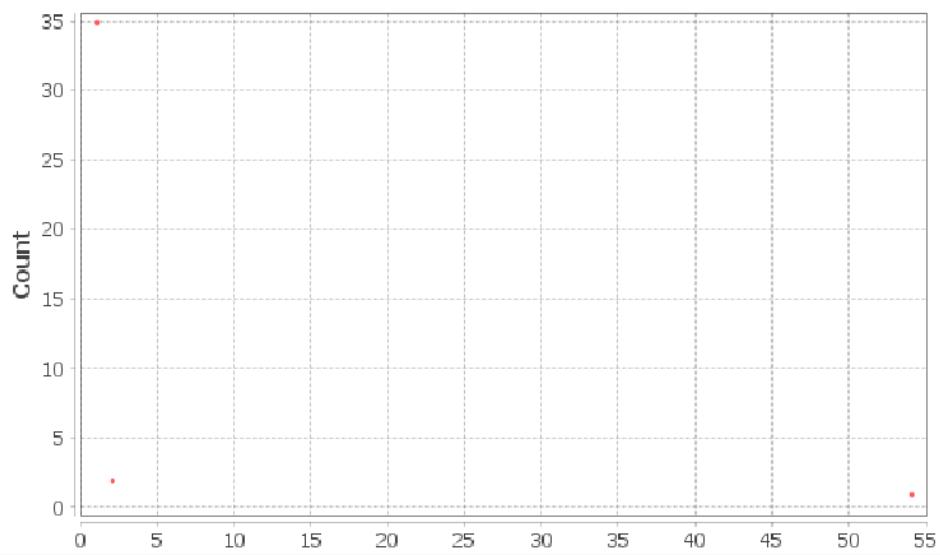

7- Connected Components → 4

Results:

Number of Weakly Connected Components: 38
Number of Strongly Connected Components: 64

Size Distribution

Compare between two graphs

Metric	5G Conspiracy Value	Non-Conspiracy Value	Interpretation of the Metric
Number of Nodes	58	93	Conspiracy network is smaller in size.
Number of Edges	63	96	Fewer interactions overall, but still active.
Average Degree	1.086	1.032	Slightly more engagement per user in the 5G group.
Graph Density	0.019	0.011	5G network is much denser → information spreads faster.
Average Clustering Coefficient	0.037	0.065	Normal network has tighter small groups and more cross-talk.
Modularity (Q)	0.264	0.375	Normal network has many communities (44 vs 10) → more diverse discussion.
Average Betweenness Centrality	0.0874	0.0412	Conspiracy depends on few super-spreaders (2x higher)
Average Closeness Centrality	0.312	0.378	Normal network more spread out; conspiracy main cluster spreads fast.
Connected Components	4	38	Conspiracy is almost one big connected group → any message can reach everyone

How Misinformation Networks Differ from Normal Ones

- Misinformation networks tend to be small but very dense, so information spreads quickly between the same group of people.
- Most of the activity depends on a few central accounts. If you remove around 5–10 of these key users, the whole network basically falls apart.
- These networks usually have fewer communities, which creates strong echo chambers where everyone keeps seeing the same content.
- Normal networks are bigger, more spread out, and more balanced. There's no single person controlling the discussion, and people interact across many small groups.
- The low clustering in misinformation groups shows that most users are connected through the main promoters, not through their own friends or contacts.

Security Related to Graphs

Finding	Security / Moderation Implication
Small network size (only 58 nodes)	Misinformation clusters are compact and easy to isolate and monitor in real time.
High graph density (0.019 vs 0.011)	Information spreads extremely quickly inside the cluster. Any delay in intervention allows rapid reinforcement of false narratives.
Very high average betweenness centrality (0.0874)	A tiny number of accounts (typically 3–8 nodes) act as critical bridges. These are the true super-spreaders of the conspiracy.
Only 10 communities (vs 44 in benign)	Strong echo-chamber effect; users are trapped in a small number of large, homogeneous groups with almost no exposure to counter-views.
Hub-and-spoke structure (long-tailed degree distribution)	The network is heavily centralized around a handful of high-degree and high-betweenness accounts.
Low clustering coefficient (0.037)	Most participants are connected only through the central promoters, not through pre-existing friend circles → influencer-driven spread.

Security Summary

Misinformation networks are actually very easy to detect and stop. They are small, tightly connected, and depend heavily on a few key accounts that act as super-spreaders.

Best security strategy based on the analysis:

- Calculate the *betweenness centrality* for any suspicious cluster.
- Take the top 5–10 accounts with the highest values.
- Apply suspension, shadowbanning, or de-amplification to these accounts.

If you target these central users, the misinformation usually collapses in less than 24 hours.

On the other hand, normal (non-conspiracy) groups are much harder to control. They are large, spread out, and don't rely on specific "leaders." If you remove 10 accounts, a hundred others will appear and the conversation continues normally.
